

## LM2405

### Monolithic Triple 7 ns CRT Driver

#### General Description

The LM2405 is an integrated high voltage CRT driver circuit designed for use in color monitor applications. The IC contains three high input impedance, wide band amplifiers which directly drive the RGB cathodes of a CRT. Each channel has its gain internally set at  $\sim 14$  and can drive CRT capacitive loads as well as resistive loads presented by other applications, limited only by the package's power dissipation.

The IC is packaged in an industry standard 11 lead TO-220 molded plastic power package. See thermal considerations on page 5.

#### Features

- Rise/fall times typically 7 ns with 8 pF load

- Output swing capability:  
50  $V_{PP}$  for  $V_{CC} = 80$   
40  $V_{PP}$  for  $V_{CC} = 70$   
30  $V_{PP}$  for  $V_{CC} = 60$
- Pinout designed for easy PCB layout
- 0V to 6V input range
- Stable with 0 pF–20 pF capacitive loads
- Convenient TO-220 staggered lead package style

#### Applications

- CRT driver for 1280 x 1024 (Non-interlaced) and XGA display resolution color monitors
- Pixel clock frequency up to 130 MHz
- Monitors using video blanking

## Theory of Operation

The LM2405 is a high voltage monolithic triple CRT driver suitable for SVGA and XGA display applications. The LM2405 features +80V operation and low power dissipation. The part is housed in the industry standard 11-lead TO-220 molded plastic power package.

The circuit diagram of the LM2405 is shown in *Figure 1*. A PNP emitter follower, Q5, provides input buffering. Q1 and Q2 form a fixed gain cascode amplifier, with a gain of  $-14$ . Emitter followers Q3 and Q4 isolate the high output impedance of the amplifier from the capacitance of the CRT cathode, and make the circuit relative insensitive to load capacitance. Q6 provides biasing to the output emitter follower stage to reduce crossover distortion at low signal levels.

*Figure 2* shows a typical test circuit for evaluation of the LM2405. This circuit is designed to allow testing of the LM2405 in a  $50\Omega$  environment, such as a pulse generator and a scope, or a network analyzer. In this test circuit, two low inductance resistors in series totaling  $4.95\text{ k}\Omega$  form a 100:1 wideband low capacitance probe when connected to a  $50\Omega$  cable and load. The input signal from the generator is AC coupled to the base of Q5.

## Application Hints

### INTRODUCTION

National Semiconductor is committed to providing application information that assists our customers in obtaining the best performance possible from our products. The following information is provided in order to support this commitment. The reader should be aware that the optimization of performance was done using a specific printed circuit board designed at National. Variations in performance can be realized due to physical changes in the printed circuit board and the application. Therefore, the designer should be aware that component value changes may be required in order to optimize performance in a given application. The values shown in this document can be used as a starting point for evaluation purposes. When working with high bandwidth circuits, good layout practices are also critical to achieving maximum performance.

### POWER SUPPLY BYPASS

Since the LM2405 is a wide bandwidth amplifier, proper power supply bypassing is critical for optimum performance. Improper power supply bypassing can result in large overshoot, ringing and oscillation. A  $0.01\text{ }\mu\text{F}$  capacitor should be connected from the supply pin,  $V_{CC}$ , to ground, as close to

## Application Hints (Continued)

the supply pin as is practical (preferably less than ¼" from the supply pin). Additionally, a 10 µF to 100 µF electrolytic capacitor should be connected from the supply pin to ground. The electrolytic capacitor should also be placed reasonably close to the LM2405's supply pin. A 0.1 µF capacitor should be connected from the bias pin,  $V_{BB}$ , to ground, as close as is practical to the part.

### ARC PROTECTION

During normal CRT operation, internal arcing may occasionally occur. Spark gaps of 200V to 300V at the cathodes will limit the maximum voltage, but to a value that is much higher than allowable on the LM2405. This fast, high voltage, high energy pulse can damage the LM2405 output stage. The addition of clamp diodes D1 and D2 (as shown in Figure 7) will help clamp the voltage at the output of the LM2405 to a safe level. The clamp diodes should have a fast transient response, high peak current rating, low series impedance and low shunt capacitance. FDH400 or equivalent diodes are recommended. Resistor R2 in Figure 7 limits the arcover current while R1 limits the current into the LM2405 and reduces the power dissipation of the output transistors when the output is stressed beyond the supply voltage. (Peaking inductor  $L_p$  also helps protect the CRT driver from arc over.) Having large value resistors for R1 and R2 would be desirable, but this has the effect of increasing rise and fall times. For proper arc protection, it is important to not omit any of the arc protection components shown in Figure 7.

FIGURE 7. One Section of the LM2405 with Arc Protection and Peaking Inductor  $L_p$

There are also ESD protection diodes built into the part. To avoid damaging these diodes, do not apply an input voltage from a low impedance source when the  $V_{BB}$  and  $V_{CC}$  pins are held at ground potential.

### IMPROVING RISE AND FALL TIMES

Because of an emitter follower output stage, the rise and fall times of the LM2405 are relatively insensitive to capacitive loading. However, the series resistors R1 and R2 (see Figure 7) will increase the rise and fall times when driving the CRT's cathode which appears as a capacitive load. The capacitance at the cathode typically ranges from 8 pF to 12 pF. To improve the rise and fall times at the cathode, a small inductor is often used in series with the output of the amplifier. The inductor  $L_p$  in Figure 7 peaks the amplifier's frequency response at the cathode, thus improving rise and fall times. It also acts with the output load capacitance to form a low pass filter, which reduces the amplitudes of high frequency harmonics of the video signal, to lower radiated electromagnetic interference. The inductor value is empirically determined and is dependent on the load. An inductor value of 0.22 µH is a good starting value. Note that excessive peak-

ing of the amplifier's frequency response will increase the overshoot. (Increasing the value of resistor R1 or R2 will reduce ringing and overshoot.)

### EFFECT OF LOAD CAPACITANCE

The output rise and fall times will be slower than specified if the load capacitance at the output is more than 8 pF, as shown in Figure 8.

FIGURE 8. Effect of Load Capacitance on Rise/Fall Time

The monitor designer should ensure that stray capacitance applied to the LM2405 is as low as possible.

### THERMAL CONSIDERATIONS

Power supply current increases as the input signal increases and consequently power dissipation also increases.

The LM2405 cannot be used without heat sinking. Typical "average" power dissipation with the device output voltage at one half the supply voltage is 2.4W per channel for a total dissipation of 7.2W package dissipation. Under white screen conditions, i.e., 25V output, dissipation increases to 3.5W per channel or 10.5W total. The LM2405 case temperature must be maintained below 100°C. If the maximum expected ambient temperature is 50°C, then a maximum heat sink thermal resistance can be calculated:

$$R_{th} = \frac{100^{\circ}\text{C} - 50^{\circ}\text{C}}{10.5\text{W}} = 4.8^{\circ}\text{C/W}$$

This example assumes a typical CRT capacitive load and is without a resistive load. Note that this thermal resistance must be achieved when the heat sink is operating in the monitor.

### INPUT RESISTANCE

The LM2405 has a fixed resistor of 3000Ω connected from each signal input pin to ground. In the Figure 2 Test Circuit, the input DC voltage level,  $V_{test}$ , must be adjusted, (to about +3.5V) to allow for the voltage drop across the 1000Ω resistor, to set the actual voltage at the input pins to +2.6V. In actual use in a monitor, the 1000Ω resistor is not used and the video preamp supplies the 2.6V offset.

### PC BOARD LAYOUT CONSIDERATIONS

For optimum performance, an adequate ground plane, isolation between channels, good supply bypassing and minimizing unwanted feedback are necessary. Also, the length of the

## Application Hints (Continued)

signal traces from the preamplifier to the LM2405 and from the LM2405 to the CRT cathode should be as short as possible. The following references are recommended:

Ott, Henry W., "Noise Reduction Techniques in Electronic Systems", John Wiley and Sons, New York, 1976.

"Guide to CRT Video Design", National Semiconductor Application Note 861.

"Video Amplifier Design for Computer Monitors", National Semiconductor Application Note 1013.

Because of its high small signal bandwidth, the part may oscillate when it is used in a typical application with a preamp in a monitor, if feedback occurs around the video amplifier through the chassis wiring. To prevent this, leads to the input

circuit should be shielded, and input circuit wiring should be spaced as far as possible from output circuit wiring. Power should be removed as quickly as possible from an amplifier that is oscillating, since power dissipation in the part is very high in this mode and the part may be damaged if oscillations continue and the power supply can supply more than 250 mA.

### TYPICAL APPLICATION

A typical application of the LM2405 is shown in *Figure 9*. Used in conjunction with an LM1205, a complete video channel from monitor input to CRT cathode can be achieved. Performance is satisfactory for all applications up to 1280x1024 non-interlaced, and pixel clock frequencies up to 130 MHz.

## LIFE SUPPORT POLICY

NATIONAL'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF THE PRESIDENT AND GENERAL COUNSEL OF NATIONAL SEMICONDUCTOR CORPORATION. As used herein:

1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body, or (b) support or sustain life, and whose failure to perform when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury to the user.
2. A critical component is any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.
